Executive Summary using SANS template:

On March 16, 2026, a high-severity vulnerability (CVE-2011-2523) was exploited against the internal VSFTPD service on host 10.0.2.3. The attack utilized a known backdoor in version 2.3.4 to attempt unauthorized command execution. The SOC detected the activity via Wazuh, and the threat was neutralized through IP-based containment.

Timestamp	**Source IP**	**Event**	**Action**
11:50:32	10.0.2.15	Escalated privileges detected	Logged
15:02:10	10.0.2.15	VSFTPD Backdoor Exploit Initiated	Alert Triggered
15:05:00	N/A	CrowdSec Isolation	Attacker Blocked

Root Cause & Technical Analysis:

The attacker used Metasploit's exploit/unix/ftp/vsftpd_234_backdoor module. Initial attempts failed to spawn a new shell because the backdoor listener on port 6200/TCP was already occupied, indicating a persistent threat or a previous successful exploit. Wazuh logs confirmed unauthorized root-level access attempts (Rule 5402) and suspicious PAM sessions.

Remediations:

1. **Patching:** Immediately upgrade VSFTPD to a version higher than 2.3.4.
2. **Network Hardening:** Implement a "Deny-All" ingress policy, only allowing port 21/22 from authorized administrative IPs.
3. **MDR:** Enabled automated active response in Wazuh to drop connections upon detection of T1190 techniques.

Stakeholder Briefing (Non-Technical):

The security monitoring system which was supposed to be an act of security camera of the system (Wazuh) flagged an unauthorized attempt to access our file server this afternoon. A known weakness in our older file-transfer software was targeted to gain administrative control.

Actions Taken:

- **Detection:** The SOC analyst identified the breach attempt within seconds.
- **Containment:** Our defense tools (CrowdSec) automatically blocked the attacker's IP address, preventing further data access.
- **Resolution:** We have verified that the attacker is no longer able to communicate with our systems.
